

This township is rough and mountainous in the western part, the mountains being rocky with many large cliffs, or outcroppings of granite and basalt, with no indications of any minerals. The land around the base of these mountains is rolling. The soil is composed of sand from decomposed granite and volcanic rock, and sagebrush and bunchgrass grows abundantly on it, - it being used by cattlemen in this vicinity for grazing purposes. The mountain sides are also covered with sagebrush and bunchgrass and there are several fine springs of water in the canyons where many head of wild horses water.

The general slope of the land is north and east, the drainage going to Rock Creek.

There is no part of this township under cultivation as there is no water available, at present, but the soil should produce good crops of grain if irrigated.

There are no settlers in this township.

John G. Collins

U.S. Transitman.

NOTE by Winfred A. Pray, U.S. Surveyor.

Where stones were used for corners instead of iron posts it was done because I had no iron posts available at the time. The lines surveyed by me were measured with 5 ch. steel tape and clinometer.
